It will be added to the database if thereâ€™s at least one game on Voobly that is exactly the same with this game as its title, list of genres and release date.Now it is widely accepted that the collection and processing of high volumes of data in business and government must be done in an efficient and timely manner. One business advantage of such an efficient collection of data is the ability to rapidly identify and resolve problems, which may occur in the course of business and to efficiently predict business trends. Likewise, it is advantageous for government to rapidly identify and resolve problems such as for example, natural disasters. To collect and process large amounts of data, it is often necessary to use a remote storage location. A remote storage location is typically a server located at a location other than the client device. Additionally, it is also advantageous for such remote storage location to have certain security features. In most cases, such a remote storage location is also called a “data center”. The terms remote storage location and data center are hereinafter used synonymously. A common method used for acquiring data from remote storage locations is to use a network storage protocol. Two such network storage protocols are Network File System (NFS) and Common Internet File System (CIFS). The NFS protocol was developed and is commonly used for accessing data stored remotely through a network. The CIFS protocol is a standard that allows files to be shared over a Local Area Network (LAN) and/or Wide Area Network (WAN). At present, to access data using a network storage protocol, a client device opens a connection through a server to the remote storage location to access the data. This process is typically called a “mount”. Unfortunately, this mount process is slow and burdensome. Typically, a client device that uses a file system or a directory service to open a connection to a remote storage location needs to login, establish communication, and communicate a password to acquire access to the remote storage location. A client device that uses the CIFS protocol requires both login and password exchanges. A login at a remote storage location includes exchanging authentication parameters such as user name and password, and establishing a session. After a session is established,
