Q: What is the percentage of upvote on questions compared to downvote? Is the percentage of upvote on questions different from downvote? I'm asking this because sometimes when I go to reviews queue, I see some good answers voted by users who didn't even post the answer. A: At least on meta Stack Overflow, the percentage of upvoted posts is higher than the percentage of downvoted posts. That said, in order to have an accept-rate for either questions or answers, we would need to know the total number of votes cast (up or down) on those posts, which is not available on the site. See also How is Stack Overflow different from other sites, for the reference. `/// Generated by class-dump 3.5 (64 bit) (Debug version compiled Oct 15 2018 10:31:50).

Q: Why isn't the contract considered a "chaincode" and why can I run it in on the server? I'm taking a course on Chaincode school and I have a question about the definition of a "chaincode". In the documentation they describe a "chaincode" as A runnable blockchain contract stored in the Ethereum blockchain However, they don't explain why this is necessary. To see why I'm asking, take this example from the school's documentation: Let's say the user has a very large number of accounts that they wish to randomly share their balance using the transferFunds function. A chaincode approach would require each of these accounts to interact with the chaincode, which could get very expensive with a large number of accounts and transfer a lot of data. Instead, we could compute the total amount that the user has and split it into a set of equal sized allocations. Then we can inform the user on the client that each allocation has been successfully set in the registry. Isn't this just a contract? Why is it not a blockchain? I understand that there's an Ethereum client written in Solidity, but this doesn't seem to negate the fact that it can be run on the server. Why can't it be run on the server? Also, why can't this contract be written in any other language and still be a blockchain contract? A: There are two different terms when it comes to Ethereum: smart contracts (aka Dapps) and blockchain-based platforms. As you mentioned, Ethereum is a platform for smart contracts. While on its own, Ethereum does not have a blockchain. It only provides the (underlying) infrastructure for running smart contracts. Think of it as a software that allows a computer to run simple programs. For example, Ethereum can be used to run a small, simple game which allows to send resources, collect resources, exchange tokens, etc. The rules can also be entered into a smart contract (much like coding the game). That smart contract could also store data from the user. In this specific example, you could have a user enter a large number of accounts. The user could then select a subset of these accounts to transfer funds to. He would do so by sending a transaction from his client (using the Ethereum JSON RPC interface) to a certain function inside the chaincode. That function
