Dugundernekfullizle720p Q: Is it practical to use a minimum of two FPGAs for a computational job? I'd like to start with a question about FPGAs and how they can be used in practice. I have a one-year course on VHDL, and I'm studying logic circuits in Verilog now. The problem with programming logic circuits is that you can't determine the amount of gates until they are finished, since you need to assume any inputs. That works fine, but I'm not sure if that means you can start with a single FPGA because you would need to be sure that you'll receive all the inputs from the outside world, and you would probably need to change the FPGA configuration, and maybe even the code depending on how it's connected. Now I have a job where I have to build a simulation and compile it. I want to use a single FPGA since I'm cheap and I don't like buying lots of hardware, and I'm not sure that's a good idea, even though I don't have much experience in this kind of design. A: The answer is that it depends. Is your question "is a one-year course on Verilog enough?" A year is long enough to learn the material and make an adequate project, but not enough to learn it fast enough to do it in a single school year. If you don't do the verilog course during the year (and you don't get paid anyway), do a Verilog course or two over the summer. Do you want to learn digital design or algorithmic design, or a mix of the two? For algorithmic design, designing directly for a verilog simulator isn't the end of the 570a42141b
