****Peak-area ratios of Leucine in plasma samples from female Sprague Dawley rats.**** Peak area ratios of Leucine from plasma samples (n = 6) were calculated based on the peak area of the m/z = 132.08, which represents the internal standard. Ratios were compared between the negative control (NC) and the remaining treatment groups (3 mg/kg, 9 mg/kg and 18 mg/kg) using two-way analysis of variance (ANOVA) with Sidak's multiple comparisons test. No significant differences were found among the NC group and the three treatment groups. (Bars represent the mean \pm SD of the mean, $\ast p < 0.05$)

The quality of aquatic wildlife habitats can be improved if we take into account the presence of drainage pipes, but only if the pipes are positioned in the right locations, according to study findings. Wildlife habitats can often be improved by taking into account the presence of drainage pipes. The findings of a Finnish study show that by knowing where drains are placed, we can do a better job of protecting nature from growing urbanisation. “For example, if roads have drainage pipes underneath, it makes sense to protect the edge of the roads or even to construct above-ground rain gardens,” says L. Räsänen (University of Helsinki), who led the study. “The presence of pipes is something that we know about, so it is possible to use this information to help protect these habitats.”
